Classifying different types of blood cells from microscopic images

Johannes Kollek & Jean-Marco Alameddine

June 5, 2018

Machine Learning for Physicists - TU Dortmund

Problem

- The task is to distinguish between four different types of white blood cells from microscopic blood test images

- Couting blood cells is an important task in diagnosing diseases

- Manual classification requires technical knowledge and is very time-consuming

$\Rightarrow$ Machine Learning provides and efficient and fast method to solve this task

Dataset

- Dataset found on Kaggle, published on
  `https://github.com/Shenggan/BCCD_Dataset`
  (MIT license)
- ≈ 12500 images including a white blood cell
- Colored $320x240$ pixels images
- Four different labels charaterizing the cell (Eosinophil, Lymphocyte, Monocyte, Neutrophil)
- Two kaggle kernels dealing with this specific dataset
- Several papers addressing this problem (with different datasets)
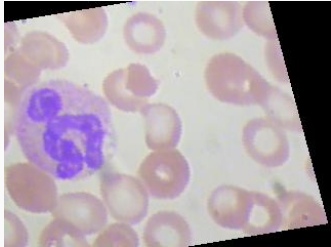

(a) Neutrophil.
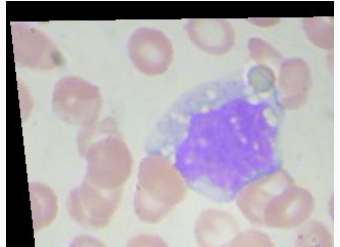

(b) Monocyte.

(c) Lymphocyte.

(d) Eosinophil.

- Using alternative methods to solve the problem...

- ... but the question is: ARE there any alternative methods that are applicable to this problem?
  (Without using an enormous amount of preprocessing)
